

Project 8: Docker

- **Project 8: Docker**
 - Goal of the project
 - GitHub repo
 - Installing Docker Desktop
- **Research**
 - Virtualisation vs containerisation
 - Benefits of virtualisation vs containerisation
 - Microservices
 - Benefits
 - Docker
 - Docker commands
 - Dockerfile
 - Docker Compose
 - Alternatives to Docker
 - Success story using Docker
- **Task 1: Learning to manage Docker containers locally**
 - Run and pull my first image
 - Run Nginx web server in a Docker container
 - Remove a container
 - Modify the Nginx default page in the running container
 - Run a different container on a different port
 - **Blockers**
- **Task 2: Using Docker Hub to host custom images**
 - Goal
 - Push host-custom-static-webpage container
 - Automate Docker image creation using a Dockerfile
 - **Blockers**
- **Task 3: Running Sparta test app in a container using Dockerfile and Docker Compose**
 - Goal
 - Initial steps and manual method
 - Automatic method 1
 - Automatic method 2
 - **Blockers**
- **Extension task: Running the containers on an EC2 instance**
 - Goal
 - Steps
 - **Blockers**
- **What I learnt from the project**
- **Benefits I personally saw from the project**

Goal of the project

- To learn how to manage Docker containers and ultimately to containerise the deployment of the Sparta test app and database using Docker and a cloud provider (AWS)

GitHub repo

[Available here](#)

Installing Docker Desktop

- I installed Docker Desktop by following the instructions on [the Docker site](#)

Research

Virtualisation vs containerisation

- **Virtualisation:** a technology allowing users to run several isolated VMs on one physical server/host machine
- **Downsides:**
 - heavier than containerisation because it requires a separate, full OS on each VM
 - uses a lot of resources
 - start-up and provisioning can be slow
- **Containerisation:** bundling (or **encapsulating**) code and all its dependencies into a **container image**
- **Container images:** pre-built packages containing everything needed to run an application, including the code, dependencies, and configuration
- An image is then run in instances called a **container**: a lightweight, standalone, & consistent executable package that includes everything needed to run a piece of software and can be reliably deployed across most systems
- An alternative to full virtualisation, containers use an abstracted OS so that they can run consistently on any machine (so unlike VMs, containers don't include full OSes)
- These containers operate in isolated environments, so they run independently from the infrastructure they're deployed into
- **Volumes:** they persistently store data for containers beyond their lifecycle; these can be easily backed up, restored, and shared between containers

Benefits of virtualisation vs containerisation

Virtualisation	Containerisation
Compared to traditional architecture , virtualisation reduces resource (hardware) costs because VMs can run on one physical machine and can be assigned only the computing power they actually need	Containers are lighter than VMs because they share the host machine's OS kernel, so they minimise resource overhead (e.g. they don't use the hypervisors that VMs do) because they don't run separate OS tasks
VMs provide high availability via monitoring and scale sets (so they are also very helpful in disaster situations)	Though VMs are portable between machines, containers are more so because they are also OS-agnostic (so long as the OSes support the containerisation tool, e.g. Docker) — <i>write once, run anywhere</i>
VMs are very scalable	The microservices approach means images are dense and often have relatively small file sizes, so they can be quicker to deploy, share, migrate, and move
Compared to containerisation , VMs are more secure than containers because they are fully isolated (i.e. vulnerabilities in one host kernel won't affect all the others thanks to using different OS kernels in each VM)	The compartmentalisation approach of microservices makes maintenance and changes to an app easier to implement

Microservices

- **Microservices** architecture: splitting large apps into loosely coupled, fine-grained services that run in their own processes and can be deployed independently
- Each microservice should be small, as independent as possible, and specialised, with a minimal set of features
- They are a lighter solution to monolith containers, in which the whole app is built into one package and deployed all or nothing
 - Once apps reach a certain size/complexity in monolith architectures, development and start-up slow down
- Microservices communicate using lightweight mechanisms like APIs
- They enable faster feature delivery and scaling for large apps

Benefits

- Microservices allow DevOps teams to introduce new components without causing downtime because microservices are independent
- Improve fault isolation
- Accelerate deployment
- Optimise resource allocation within organisations because teams work on small, well-defined services

Docker

- **Docker:** an open-source platform designed to help build, share, and run container apps

- **Official images:** images curated by Docker; typically well-maintained and documented so a good choice for beginners
- **Docker Hub:** a cloud-based registry service **serving as a central repository** where Docker users and orgs can find, store, and share their Docker images - **Docker Engine:** The core technology that runs and manages containers on a machine
- **Tags:** aliases that point to versions of an image (e.g. *latest*, *2.1*, or *Linux*); when you don't specify a tag in your commands, Docker assumes you want the "*latest*" tag
- Benefits of tags:
 - Useful for **version control** because you can tag images with version numbers (e.g. v1, v2)
 - Useful for **environment separation** because you might tag images for different environments (e.g. dev, staging, prod)
 - **Readability:** custom tags can make it clearer what an image is for
- **Pull command:** On each image's page, there is a "pull command"; this is what you'd use to manually download the image without running a container; e.g. `docker pull hello-world`

```
Farah@Farah-laptop MINGW64 ~  
$ docker pull hello-world  
Using default tag: latest  
latest: Pulling from library/hello-world  
e6590344b1a5: Download complete  
Digest: sha256:e0b569a5163a5e6be84e210a2587e7d447e08f87a0e90798363fa44a0464a1e8  
Status: Downloaded newer image for hello-world:latest  
docker.io/library/hello-world:latest
```

- Docker images are built using a **layered filesystem**, with each layer representing a command in the Dockerfile used to build the image
 - this layered approach allows Docker to be efficient with storage and network usage
 - each layer is represented by a long string (called a SHA256 hash)
 - they are cached, speeding up builds of similar images
 - when pushing or pulling images, only changed layers are transferred

Diagram by Labex:

Docker commands

[Common Docker commands](#)

Dockerfile

- **Dockerfile**: a text file that contains all the commands/instructions used to build a Docker image; can be helpful to understand how the image was created
- these are named with a capital D and have no extension
- each container directory **can only have one** Dockerfile
- A Dockerfile includes the **base image** to be used, **commands** telling Docker how to set up the image, and the **start up** command
- must begin with a **FROM** instruction, which specifies the base image to be built from
- other common instructions include **RUN** e.g. to install dependencies, **COPY** to copy local files into the image, **EXPOSE** which tells Docker that the container listens on a given port, and **CMD** which defines the default command to run on start-up
- an **ENTRYPOINT** instruction can also reference a script file to specify the commands to be run when the container starts, e.g.

```
FROM nginx
ENV NGINX_PORT 9100
COPY start.sh /start.sh
RUN chmod +x /start.sh
ENTRYPOINT ["/start.sh"]
```

- you must then also create the file referenced in the ENTRYPOINT instruction (i.e. `/start.sh` here)

Docker Compose

- **Docker Compose:** a YAML file that allows you to run multi-container apps and manage each container simultaneously
- allows these linked containers to be spun up or torn down with `docker compose up` and `docker compose down` (there are also optional flags that can be used with these commands; [see here](#))
- standard name is `compose.yml` or `compose.yaml`
- example syntax:

```
services:
  app:
    image: <image name:optional tag>
    container_name: <optional container name>
    environment:
      - <optional environment variable>
    ports:
      - <ports to be used by service>
    depends_on:
      - <another service defined in the Compose file that is required for this service>
```

- other than `services`, blocks could be `networks`, `volumes`, `configs`, or `secrets`

Alternatives to Docker

- **Podman:**
 - developed by RedHat
 - daemon-less, so doesn't need root privileges and thus reduces attack surfaces
 - fully open-source (whereas Docker requires licenses for orgs with 150+ employees or \$10+ million revenue)
 - but less support for non-Linux OSes
- **Rancher Desktop:**
 - fully open-source
 - Kubernetes-focused (which can be a pro and a con)
 - has a GUI for Kubernetes, so is more beginner-friendly

Success story using Docker

- Uber uses Docker for microservices for passenger management, billing, driver management, trip management, and notifications

Task 1: Learning to manage Docker containers locally

Run and pull my first image

1. Get help from a `docker` command

```
farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-ench-udemy-pathways/Project 8 (main)
$ docker --help

Usage:  docker [OPTIONS] COMMAND

A self-sufficient runtime for containers

Common Commands:
  run       Create and run a new container from an image
  exec      Execute a command in a running container
  ps        List containers
  build     Build an image from a Dockerfile
  pull     Download an image from a registry
```

2. Run a `docker` command to show all the images I have on my local machine

```
farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-ench-udemy-pathways/Project 8 (main)
$ docker images
```

REPOSITORY	TAG	IMAGE ID	CREATED	SIZE
project8-app-db-method2	latest	1745ccad5954	3 hours ago	1.7GB
farahc123/sparta-app	v1	95c36fe3ca41	26 hours ago	1.66GB
farahc123/nginx-dreamteam	latest	9845584b7449	30 hours ago	323MB
mongo	latest	961312ca9515	3 days ago	1.19GB
nginx	latest	9d6b58feebd2	2 weeks ago	279MB
hello-world	latest	e0b569a5163a	4 weeks ago	20.4kB
daraymonsta/nginx-257	dreamteam	aca9f1774d81	10 months ago	313MB
mongo	7.0	048559287a51	55 years ago	270MB

3. Run my first Docker container using the `hello-world` image and then re-run the image to see that it doesn't need to be downloaded again

```
farah@Farah-laptop MINGW64 ~
$ docker images
REPOSITORY    TAG                IMAGE ID           CREATED          SIZE

farah@Farah-laptop MINGW64 ~
$ docker run hello-world
Unable to find image 'hello-world:latest' locally
latest: Pulling from library/hello-world
e6590344b1a5: Download complete
Digest: sha256:e0b569a5163a5e6be84e210a2587e7d447e08f87a0e90798363fa44a0464a1e8
Status: Downloaded newer image for hello-world:latest

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (amd64)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
$ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:
https://hub.docker.com/

For more examples and ideas, visit:
https://docs.docker.com/get-started/

farah@Farah-laptop MINGW64 ~
$ docker run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.
```

Run Nginx web server in a Docker container

1. Download the latest Nginx Docker image using a `docker pull` command, run it so that it exposes the running container on port 80 on my local machine, and run a `docker ps` command to check if it's

running

```

farah@Farah-laptop MINGW64 ~
$ docker pull nginx
Using default tag: latest
latest: Pulling from library/nginx
84cade77a831: Download complete
6c78b0ba1a32: Download complete
c558df217949: Download complete
24ff42a0d907: Download complete
c29f5b76f736: Download complete
e19db8451adb: Download complete
976e8f6b25dd: Download complete
Digest: sha256:91734281c0ebfc6f1aea979cffee5079cfe786228a71cc6f1f46a228cde6e34
Status: Downloaded newer image for nginx:latest
docker.io/library/nginx:latest

farah@Farah-laptop MINGW64 ~
$ docker run -d -p 80:80 nginx:latest
2ff9f5014b6fb6de85cb137c1d37a76fd23d6a06fb3ff571af0b124e78afecda

farah@Farah-laptop MINGW64 ~
$ docker ps
CONTAINER ID   IMAGE      COMMAND                  CREATED        STATUS        PORTS                    NAMES
2ff9f5014b6f   nginx:latest  "/docker-entrypoint..."  9 seconds ago  Up 8 seco    0.0.0.0:80->80/tcp      nervous_mcclintock

```

2. Check it's working by going to *localhost* or *127.0.0.1* in a web browser

Welcome to nginx!

If you see this page, the nginx web server is successfully installed and working. Further configuration is required.

For online documentation and support please refer to nginx.org.
Commercial support is available at nginx.com.

Thank you for using nginx.

3. Stop the container running

```

farah@Farah-laptop MINGW64 ~
$ docker ps
CONTAINER ID   IMAGE      COMMAND                  CREATED        STATUS        PORTS                    NAMES
2ff9f5014b6f   nginx:latest  "/docker-entrypoint..."  About a minute ago  Up About a minute  0.0.0.0:80->80/tcp      nervous_mcclintock

farah@Farah-laptop MINGW64 ~
$ docker stop 2ff9f5014b6f
2ff9f5014b6f

farah@Farah-laptop MINGW64 ~
$ docker ps
CONTAINER ID   IMAGE      COMMAND                  CREATED        STATUS        PORTS                    NAMES
farah@Farah-laptop MINGW64 ~
$ |

```

Remove a container

1. Re-start the Nginx container I was previously running and, while it's running, try to remove the container with `docker rm` – take note of the error

```

farah@Farah-laptop MINGW64 ~
$ docker run -d -p 80:80 --name my-nginx nginx
17e2e9b0abc402a328499dc87a638bcb401ae9c327675f8c33b57f3e81de9ff4

farah@Farah-laptop MINGW64 ~
$ docker rm my-nginx
Error response from daemon: cannot remove container "/my-nginx": container is running: stop the container before removing or force remove

```

2. Work out the switch/option needed to use to forcibly remove a container while it's running

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-h
ench-udemy-pathways/Project 8 (main)
$ docker rm -f my-nginx

```

3. Run the `docker` command to check whether the container is still there

```

farah@Farah-laptop MINGW64 ~
$ docker ps -a
CONTAINER ID   IMAGE      COMMAND                  CREATED        STATUS        PORTS        NAMES
farah@Farah-laptop MINGW64 ~

```

Modify the Nginx default page in the running container

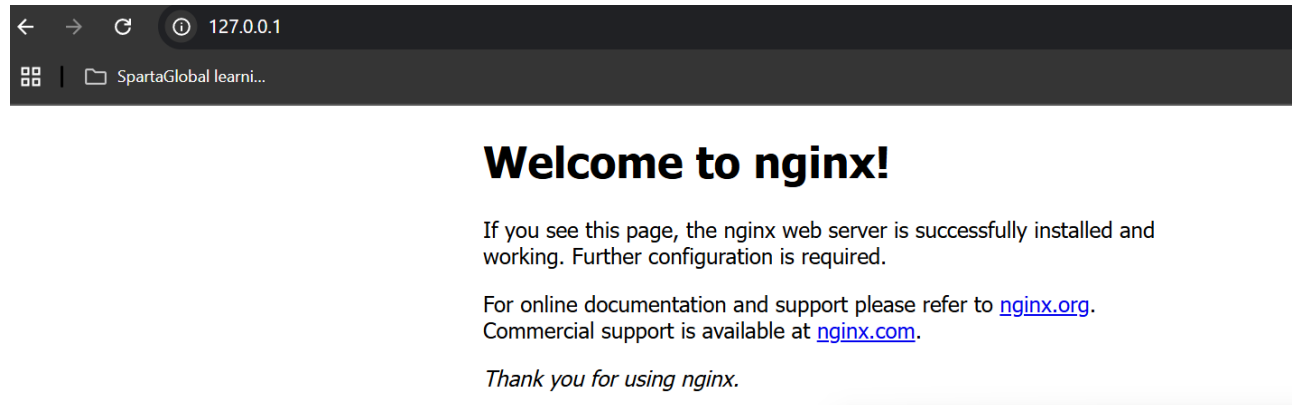

1. Re-run the Nginx container exposed on port 80 of my local machine

```

farah@Farah-laptop MINGW64 ~
$ docker run -d -p 80:80 --name my-nginx nginx
41869e9da7ade1e4e89f41480f7e81d6441dda34622dfe24aded6084d799b359

```

2. Check the default webpage of the container in my web browser and keep it open for later

The screenshot shows a web browser window with the address bar set to `127.0.0.1`. The page title is "SpartaGlobal learni...". The main content of the page is:

Welcome to nginx!

If you see this page, the nginx web server is successfully installed and working. Further configuration is required.

For online documentation and support please refer to nginx.org.
Commercial support is available at nginx.com.

Thank you for using nginx.

3. Access the shell of the Nginx container that is running with `docker exec -it my-nginx sh` (use `sh`

```

farah@Farah-laptop MINGW64 ~
$ docker exec -it my-nginx sh
#
not /bin/sh/

```

4. After logging into the shell of the Nginx container, try to do an update & upgrade with `sudo` — notice the problem, then install `sudo` to fix it (had to do `apt update` first then install `sudo`)

```
# sudo apt update && apt upgrade -y
sh: 3: sudo: not found
# apt update
Get:1 http://deb.debian.org/debian bookworm InRelease [151 kB]

0 upgraded, 3 newly installed, 0 to remove and 0 not upgraded.
Need to get 838 kB of archives.
After this operation, 3339 kB of additional disk space will be used.
Do you want to continue? [Y/n] y
Get:1 http://deb.debian.org/debian bookworm/main amd64 libncursesw6 amd64 6.4-4
[134 kB]
Get:2 http://deb.debian.org/debian bookworm/main amd64 nano amd64 7.2-1+deb12u1
[690 kB]
Get:3 http://deb.debian.org/debian bookworm/main amd64 libgpm2 amd64 1.20.7-10+b
1 [14.2 kB]
Fetched 838 kB in 0s (1991 kB/s)
debconf: delaying package configuration, since apt-utils is not installed
Selecting previously unselected package libncursesw6:amd64.
(Reading database ... 7723 files and directories currently installed.)
```

6. Once **nano** works, modify the HTML of the file so that instead of "Welcome to nginx!" the home page reads "Welcome to the Tech 501 Dreamteam!" – save my changes

```
# cat /usr/share/nginx/html/index.html
<!DOCTYPE html>
<html>
<head>
<title>Welcome to the Tech 501 Dreamteam!</title>
<style>
html { color-scheme: light dark; }
body { width: 35em; margin: 0 auto;
font-family: Tahoma, Verdana, Arial, sans-serif; }
</style>
</head>
<body>
<h1>Welcome to the Tech 501 Dreamteam!</h1>
<p>If you see this page, the nginx web server is successfully installed and
working. Further configuration is required.</p>
```

7. Check how the default web page in the browser has changed

Welcome to the Tech 501 Dreamteam!

If you see this page, the nginx web server is successfully installed and working. Further configuration is required.

For online documentation and support please refer to nginx.org.
Commercial support is available at nginx.com.

Thank you for using nginx.

Run a different container on a different port

1. Try to run another container exposed on port 80 on my local machine (connect to port 80 inside the container) using `daraymonsta/nginx-257:dreamteam`

```
Farah@Farah-laptop MINGW64 ~
$ docker run -d -p 80:80 daraymonsta/nginx-257:dreamteam
Unable to find image 'daraymonsta/nginx-257:dreamteam' locally
dreamteam: Pulling from daraymonsta/nginx-257
305d309a0ba5: Download complete
6fcdffcd79f0: Download complete
c9590dd9c988: Download complete

elastic_banach
41869e9da7ad   nginx     "/docker-entrypoint...." 29 minutes ago Up 8 minutes
0.0.0.0:80->80/tcp   my-nginx

Farah@Farah-laptop MINGW64 ~
$ docker rm ccd4b481ded8
ccd4b481ded8

Farah@Farah-laptop MINGW64 ~
$ docker ps -a
CONTAINER ID   IMAGE      COMMAND                  CREATED        STATUS
PORTS         NAMES
41869e9da7ad   nginx     "/docker-entrypoint...." 30 minutes ago Up 9 minutes
0.0.0.0:80->80/tcp   my-nginx
```

3. Try to run the container from step 2 again but this time, expose it on my local machine on port 90 with `docker run -d -p 90:80 daraymonsta/nginx-257:dreamteam`; check this container is running in my web browser at `localhost:90`

Blockers

1. On the [Nginx modification task](#), I ran into this error when running an interactive command to enter the container's shell for the first time because Git Bash has issues with TTY-based commands (i.e. it was trying to use a Windows Git Bash path instead of the correct shell inside the Nginx container)

```
farah@Farah-laptop MINGW64 ~  
$ docker exec -it my-nginx /bin/sh  
OCI runtime exec failed: exec failed: unable to start container process: exec: '  
C:/Program Files/Git/usr/bin/sh': stat C:/Program Files/Git/usr/bin/sh: no such  
file or directory: unknown
```

- To solve this, I installed **winpty**, a Windows software package that prevents these errors when running interactive commands
- By default, I would then have had to preface every interactive command with **winpty**, so I

```
farah@Farah-laptop MINGW64 ~  
$ alias docker="winpty docker"
```

created an alias which I added to the `.bashrc` file

2. I also had issues trying to use the `/bin/sh/` shell in my `docker exec -it` command, so I switched to

```
farah@Farah-laptop MINGW64 ~  
$ docker exec -it my-nginx sh  
sh# |
```

3. I had an "Unable to locate package sudo" error because the Nginx Docker image is based on Debian Slim, which doesn't include **sudo** by default

```
# sudo apt update && apt upgrade -y
sh: 3: sudo: not found
# apt update
Get:1 http://deb.debian.org/debian bookworm InRelease [151 kB]
Get:2 http://deb.debian.org/debian bookworm-updates InRelease [55.4 kB]

#
```

- I had the same issue with `nano`, which I solved by installing it with `sudo apt install nano`

Task 2: Using Docker Hub to host custom images

Goal

- To easily access, store, and share images via Docker Hub's central repository

Push host-custom-static-webpage container

1. Create an image from the running Nginx container with the modified *index.html* file and push it image to my Docker Hub account

```

farah@Farah-laptop MINGW64 ~
$ docker commit my-nginx farahc123/nginx-dreamteam
sha256:9845584b74497d2d84170c513d98e173c5137c225652ccf5b85e595a08fb0f87

farah@Farah-laptop MINGW64 ~
$ docker login
Authenticating with existing credentials...
Login Succeeded

farah@Farah-laptop MINGW64 ~
$ docker push farahc123/nginx-dreamteam
Using default tag: latest
The push refers to repository [docker.io/farahc123/nginx-dreamteam]
eefef33fde88: Pushed
c558df217949: Mounted from library/nginx
24ff42a0d907: Mounted from library/nginx
6c78b0ba1a32: Mounted from library/nginx
c29f5b76f736: Mounted from library/nginx
e19db8451adb: Mounted from library/nginx
84cade77a831: Mounted from library/nginx
976e8f6b25dd: Mounted from library/nginx
latest: digest: sha256:9845584b74497d2d84170c513d98e173c5137c225652ccf5b85e595a08fb0f87 size: 2042

```

2. Use a `docker` command to run the container using the above pushed container image, which contains my username on Docker Hub

```

farah@Farah-laptop MINGW64 ~
$ docker images
REPOSITORY          TAG          IMAGE ID          CREATED
farahc123/nginx-dreamteam  latest      9845584b7449      About a minute
nginx                latest      91734281c0eb      2 weeks ago
hello-world          latest      e0b569a5163a      4 weeks ago
daraymonsta/nginx-257    dreamteam   aca9f1774d81      10 months ago

farah@Farah-laptop MINGW64 ~
$ docker run -d farahc123/nginx-dreamteam
81c5348ccb5196c26cc203d255d0f39a88d8182f6e76e04bc21807bc14897b1f

```

Automate Docker image creation using a Dockerfile

1. To create a Dockerfile in the *tech501-mod-nginx-dockerfile* repo (that won't get Git-pushed), run `nano Dockerfile` (with no extensions)

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ ls
Dockerfile  index.html

```

2. Create an *index.html* file to use instead of the Nginx default page

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ cat index.html
<!DOCTYPE html><html><head><title>Welcome to the Tech 501 Dreamteam!</title></head><body><h1>Welcome to the Tech 501 Dreamteam!</h1></body></html>

```

3. Create a Dockerfile to use the Nginx base image, copy the *index.html* to the location of the Nginx default page in the container, use a `docker build` command to build the custom image, and tag it as *tech501-nginx-auto:v1*

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ echo '<!DOCTYPE html><html><head><title>Welcome to the Tech 501 Dreamteam!</title></head><body><h1>Welcome to the Tech 501 Dreamteam!</h1></body></html>' > index.html

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ ls
index.html

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ nano Dockerfile

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ ls
Dockerfile  index.html

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker build -t tech501-nginx-auto:v1
ERROR: "docker buildx build" requires exactly 1 argument.
See 'docker buildx build --help'.

Usage:  docker buildx build [OPTIONS] PATH | URL | -

Start a build

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker build -t tech501-nginx-auto:v1 .

```

- tagging image before pushing

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker tag tech501-nginx-auto:v1 farahc123/tech501-nginx-auto:v1

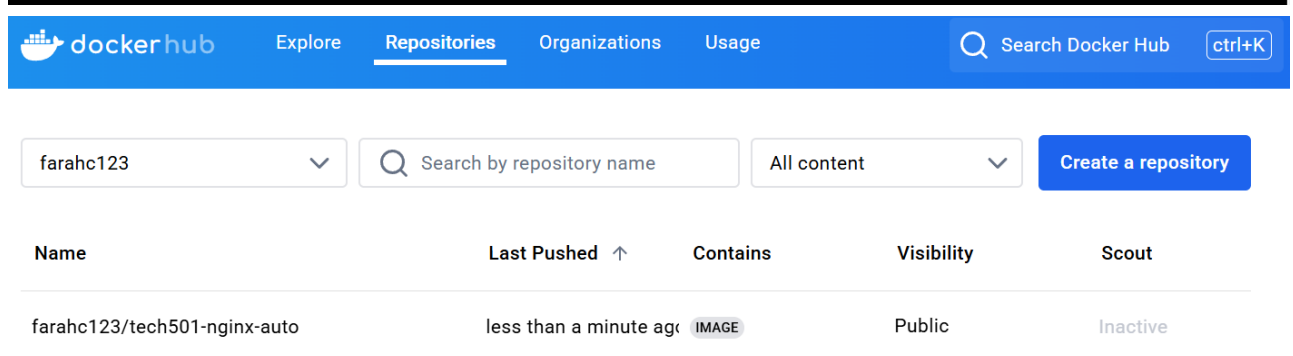

```

4. Push the custom image to Docker Hub

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker push farahc123/tech501-nginx-auto:v1
The push refers to repository [docker.io/farahc123/tech501-nginx-auto]
c558df217949: Mounted from farahc123/nginx-dreamteam
c29f5b76f736: Mounted from farahc123/nginx-dreamteam
e19db8451adb: Mounted from farahc123/nginx-dreamteam
976e8f6b25dd: Mounted from farahc123/nginx-dreamteam
84cade77a831: Mounted from farahc123/nginx-dreamteam
4e8fc9e2aea8: Pushed
55b46b75c58d: Pushed
6c78b0ba1a32: Mounted from farahc123/nginx-dreamteam
24ff42a0d907: Mounted from farahc123/nginx-dreamteam
v1: digest: sha256:08cbda84cc3c04fb733f42580c148aa64e8b61c3b6aaa83d20b9f6a80aea2ff7 size: 856

```

5. Use a `docker` command to run the container which uses the pushed custom image

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker run -d -p 80:80 farahc123/tech501-nginx-auto:v1
3335733be63dd8e9dbb95fe7b639a757bd2526b366c628f2379bbd3a3ce05a67

```

6. Remove the local copy of the custom image with `docker rmi farahc123/tech501-nginx-auto:v1`

```

farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/tech501-mod-nginx-dockerfile
$ docker rmi farahc123/tech501-nginx-auto:v1
Untagged: farahc123/tech501-nginx-auto:v1

```

7. Re-run the container and force Docker to pull the custom image from Docker Hub

```

$ docker images
REPOSITORY          TAG          IMAGE ID          CREATED          SIZE
farahc123/nginx-dreamteam  latest      9845584b7449     About an hour ago  323MB

```

Blockers

- I originally didn't tag my image, so I needed to run a `docker tag` before I could push it

Task 3: Running Sparta test app in a container using Dockerfile and Docker Compose

Goal

- To containerise the deployment of the Sparta test app and the database using Docker

Initial steps and manual method

1. Create a [folder](#) for this task (because you can only have one Dockerfile per folder)

```
farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-bench-udemy-pathways/Project 8 (main)
$ ls
'Docker repo'/  Notes.md  README.md  image.png  images/
```

2. Create a [Dockerfile](#) and a [Docker Compose file](#) in the above folder
3. Build the image, and notice that the posts hasn't been seeded on *localhost:3000/posts* (this is expected)

Recent Posts

4. To remedy this, seed the */posts* page manually with `docker exec -it sparta-app-container node seeds/seed.js`

```
farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-bench-udemy-pathways/Project 8/Docker repo (main)
$ docker exec -it farah-sparta-app-container node seeds/seed.js
Connected to database
Database cleared
Database seeded with 100 records
Database connection closed
```

- This worked:

A eaque aspernatur accusamus dolorem omnis itaque excepturi. Ducimus qui molestiae itaque aut ducimus distinctio perferendis nemo.

Automatic method 1

- Automatically seeding the database using a start-up script referenced in the Dockerfile ([all files here](#)):
 - **Compose file:**

```
compose.yml
  Run All Services
1  services:
  Run Service
2    app:
3      image: farahc123/sparta-app:v1
4      container_name: farah-sparta-app-container
5      environment:
6        - DB_HOST=mongodb://db:27017/posts # MongoDB connection string
7      ports:
8        - "3000:3000" # Exposes port 3000 for Node.js app
9      depends_on:
10       - db
11      command: ["/bin/sh", "-c", "npm install && node seeds/seed.js && npm start"]
12
  Run Service
13   db:
14     image: mongo:latest
15     container_name: mongodb-container
16     ports:
17       - "27017:27017" # Exposes port 27017 for MongoDB container
18     volumes:
19       - mongo_data:/data/db # Persists MongoDB data in a volume
20
21   volumes:
22     mongo_data: # Defines a volume for MongoDB data
23
```

- Dockerfile:

```
1  # Using NodeJS version 20
2  FROM node:20
3
4  # Adding metadata to the image
5  LABEL description="Farah's image of the Sparta test app"
6
7  # Sets the default working directory
8  WORKDIR /usr/src/app
9
10 # Copies the app's dependencies and then the app
11 COPY package*.json ./
12 COPY app/ .
13
14 # Installs dependencies
15 RUN npm install
16
17 # Exposes port 3000
18 EXPOSE 3000
19
20 # Sets the startup command
21 COPY start.sh .
22 RUN chmod +x start.sh
23 CMD ["/start.sh"]
```

```
#!/bin/sh
npm install
node seeds/seed.js
npm start
```

- **start.sh:**

Automatic method 2

- Automatically seeding the database using a health-check on the MongoDB container in my Docker Compose file ([all files here](#)):

- Compose file:

```
compose.yaml
  > Run All Services
1  services:
  > Run Service
2    app:
3      build:
4        context: .
5        args:
6          - DB_HOSTS=mongodb://mongo_db:27017/posts # Define DB_HOSTS before build
7      container_name: sparta-test-app
8      ports:
9        - "3000:3000" # Expose Node.js directly (for debugging)
10     depends_on:
11       mongo_db:
12         condition: service_healthy # Ensure MongoDB is fully ready before app starts
13     environment:
14       - DB_HOST=mongodb://mongo_db:27017/posts
15
16  > Run Service
17  mongo_db:
18    image: mongo:latest
19    container_name: mongodb
20    restart: always
21    ports:
22      - "27017:27017" # Optional, only needed if you want to connect to MongoDB from your local machine
23    volumes:
24      - mongo_db_data:/data/db # Persist MongoDB data
25    healthcheck: # Add health check to ensure MongoDB is fully ready before app starts
26      test: ["CMD", "mongosh", "--eval", "db.runCommand({ ping: 1 })"]
27      interval: 10s
28      retries: 5
29      start_period: 20s
30
31  volumes:
32    mongo_db_data:
```

- **Dockerfile:**

```
Dockerfile > ...
1 FROM node:latest
2
3 # Set working directory
4 WORKDIR /usr/src/app
5
6 # Copy your Node.js application into the container
7 COPY ./app/ /usr/src/app/
8
9 # Expose the port (assuming your Node.js app listens on 3000)
10 EXPOSE 3000
11
12 # Install dependencies & start app (ensures MongoDB is ready)
13 CMD npm install && npm start
```

- **Results:**

- I later edited my files to add Nginx in order to configure a reverse proxy:

■ Dockerfile:

```
compose.yaml
  ▸ Run All Services
1  services:
  ▸ Run Service
2    nginx:
3      image: nginx:latest
4      ports:
5        - "80:80" # Forward external traffic to nginx
6      volumes:
7        - ./nginx/nginx.conf:/etc/nginx/nginx.conf:ro # Use custom nginx config
8      depends_on:
9        - app
  ▸ Run Service
10   app:
11     build:
12       context: .
13       args:
14         - DB_HOSTS=mongodb://mongo_db:27017/posts # Define DB_HOSTS before build
15     container_name: sparta-test-app
16     ports:
17       - "3000:3000" # Expose Node.js directly (for debugging)
18     depends_on:
19       mongo_db:
20         condition: service_healthy # Ensure MongoDB is fully ready before app starts
21     environment:
22       - DB_HOST=mongodb://mongo_db:27017/posts
23
```

■ Compose file:

```
services:
  ▸ Run Service
  nginx:
    image: nginx:latest
    ports:
      - "80:80" # Forward external traffic to nginx
    volumes:
      - ./nginx/nginx.conf:/etc/nginx/nginx.conf:ro # Use custom nginx config
    depends_on:
      - app
  ▸ Run Service
  app:
    build:
      context: .
      args:
        - DB_HOSTS=mongodb://mongo_db:27017/posts # Define DB_HOSTS before build
    container_name: sparta-test-app
    ports:
      - "3000:3000" # Expose Node.js directly (for debugging)
    depends_on:
      mongo_db:
        condition: service_healthy # Ensure MongoDB is fully ready before app starts
    environment:
      - DB_HOST=mongodb://mongo_db:27017/posts

  ▸ Run Service
  mongo_db:
    image: mongo:latest
    container_name: mongodb
    restart: always
    ports:
      - "27017:27017" # Optional, only needed if you want to connect to MongoDB from your local machine
    volumes:
      - mongo_db_data:/data/db # Persist MongoDB data
    healthcheck: # Add health check to ensure MongoDB is fully ready before app starts
      test: ["CMD", "mongosh", "--eval", "db.runCommand({ ping: 1 })"]
      interval: 10s
      retries: 5
      start_period: 20s

volumes:
  mongo_db_data:
```

- **Results** (note the lack of :3000 in the URL):

Blockers

- I ran into some issues getting the automatic methods to work, which turned out to be syntax issues, so these were easily fixable

Extension task: Running the containers on an EC2 instance

Goal

- To containerise the deployment of the Sparta test app and the database using Docker and AWS
- This replicates a possible production task (deploying the app onto a VM)

Steps

1. After creating an EC2 instance running on Ubuntu 22.04, install Docker via the CLI using [these steps](#)
2. Add myself to the Docker group on my EC2 to avoid having to use `sudo` for every `docker` command following [these steps](#)
3. On my local machine, create a `tar` file with `docker save -o sparta-app-image.tar project8-app-db-method2` — this saves the Sparta test app image to a file that I can then transfer to my EC2 instance (note that I could also use a `docker pull` command, but I did it this way to try an alternative method)
4. `scp` this `tar` file to the EC2 instance using `scp -i <path to private SSH key> sparta-app-image.tar ubuntu@<EC2's public IP>:~`

```
farah@Farah-laptop MINGW64 ~/OneDrive - Sparta Global/Documents/Github/tech501-bench-udemy-pathways/Project 8/automatic method 1 docker (main)
$ scp -i ~/.ssh/tech501-farah-aws-key.pem sparta-app-image.tar ubuntu@ec2-52-215-19-68.eu-west-1.compute.amazonaws.com:~
sparta-app-image.tar                                0% 255KB 248.5KB/s   27:19 ETA|
```

5. Once this `tar` file is on the EC2 instance, load the image from it with `docker load -i sparta-app-image.tar`
6. Modify the original Dockerfile to make it work with the `tar` file (i.e. by removing the `COPY app/ .` command; see below for explanation)

```
# Using NodeJS version 20
FROM node:20

# Adding metadata to the image
LABEL description="Farah's image of the sparta test app"

# Sets the default working directory
WORKDIR /usr/src/app

# Exposes port 3000
EXPOSE 3000

# Sets startup command
CMD ["npm", "start"]
```

7. Replicate my original Docker Compose file

```
services:
  app:
    image: farahc123/sparta-app:v1
    container_name: farah-sparta-app-container
    environment:
      - DB_HOST=mongodb://db:27017/posts # MongoDB connection string
    ports:
      - "3000:3000" # Exposes port 3000 for Sparta test app
    depends_on:
      - db
    command: ["/bin/sh", "-c", "npm install && node seeds/seed.js && npm start"]

  db:
    image: mongo:latest
    container_name: mongodb-container
    ports:
      - "27017:27017" # Exposes port 27017 for MongoDB container
    volumes:
      - mongo_data:/data/db # Persists MongoDB data in a volume

volumes:
  mongo_data: # Defines a volume for MongoDB data
```

8. Build the image with `docker build -t sparta-app .` and run the containers with `docker compose up -d`

9. Results: working `/posts` page

Blockers

- I realised I had to add myself to the Docker group to give myself the correct permissions so that I didn't need to preface every `docker` command with `sudo`
- I also realised I couldn't just reuse my original Dockerfile because I no longer needed to copy the Sparta test app folder (this was referenced in my `COPY app/ .` command) as I already had this in the `tar` file, so I had to edit my Compose file

What I learnt from the project

- How Docker containers and images work
- The `docker compose up` and `docker compose down` commands work similarly to `terraform apply` and `terraform destroy` in that they build containers (and default networks) from a Docker compose file and then stop and remove everything that `docker compose up` built
- About saving images to `tar` files and how this is helpful when sharing images outside of a registry or for backing up
- That, on Linux OSes, you have to add yourself to the Docker group in order to avoid having to preface every `docker` command with `sudo`

Benefits I personally saw from the project

- After the learning curve, using Docker seems like a much easier process than the previous methods for deployment that we used
- On the [Sparta container task](#), I preferred my first automatic method command as it was simpler, so I used this as the basis for the EC2 extension task
